Government thereby incurs no responsibility, nor any obligation whatsoever; and the fact that the Government may have formulated, furnished, or in any way supplied the said drawings, specifications, or other data is not to be regarded by implication or otherwise as in any manner licensing the holder or any other person or corporation, or conveying any rights or permission to manufacture, use or sell any patented invention that may in any way be related thereto.

Pribory i metody dlia izucheniia elektrichstva atmosfery
(Instruments and methods for investigating atmospheric electricity),
Moscow, Gostekhizdat, 1957. 484 pp., cloth.

by

I. M. Imianitov

Translator: David Kraus
April 1961

Translated for Geophysics Research Directorate, Air
Force Research Division, L. G. Hanscom Field, Bedford,
Massachusetts, by the American Meteorological Society,
Contract number AF 19(604)-6113.

CATALOGED BY ASTIA

AS AD No. 258074

61-3-4
XEROX

M-RTC-29+

Imianitov, I. M. Pribory i metody dlia izucheniia elektrichestva atmosfery
(Instruments and methods for investigating atmospheric
electricity), Moscow, Gostekhizdat, 1957. 484 pp. cloth.
13 rubles 80 kopeks (about \$1.50)

TABLE OF CONTENTS

	Page
Introduction	7
Chapter 1. Mechanical electrometers	11
1. Methods of measuring small currents and voltages created by low-power sources	11
a) Measurement of the current by the voltage drop	12
b) Measurement of the current by the capacitor potential	14
2. The operating principle of mechanical electrometers	16
3. Electrometers without an auxiliary field	19
4. Electrometers with an auxiliary field	28
Chapter 2. Tube electrometers	50
5. Characteristics of tube amplifiers during their operation in measuring circuits	50
6. Features of tube circuits which operate under electrometer conditions	68
Chapter 3. Measurements of the ionization of the atmosphere	92
7. Theory of operation of ionization chambers	93
8. Measurements of alpha-emissions	98
9. Measurements of beta-emissions	102
10. Measurements of gamma radiations and cosmic radiation	104
11. Measurements of separate radiation pulses by means of ionization chambers	112
12. Proportional counters	115
13. Counters with independent discharge	118
14. Measurements of the radioactivity of precipitation	126
15. Measurements of atmospheric radioactivity	129
Chapter 4. Measurement of electrostatic fields in the atmosphere	137
16. Measurements of the potential in the atmosphere and indirect methods of measuring the electrostatic field strength	138

Chapter 4. (cont'd)	
a) Collectors that increase the conductivity of the medium	140
1. Radioactive collectors	143
2. Flame collectors	146
3. Collectors operating on coronal discharge	147
4. Electron collectors	147
b) Collectors which do not change the conductivity of the medium	147
c) Sources of error in measuring with collectors	151
d) Measurements made with collectors	156
e) Use of tube electrometers in collector measurements	163
17. Methods of indirect measurement of the electrostatic field strength in the atmosphere	169
a) Static method	169
b) Instruments based on the static method	172
c) Dynamic method	176
d) Instruments for measuring field strength based on the dynamic method	189
e) Methods of determining the sign of the field. Increasing measurement accuracy	201
f) Electrostatic fluxmeters without moving parts	207
g) Low-inertia electrostatic fluxmeters	208
h) Measurement of the electrostatic field components in the atmosphere	212
i) Fluxmeter measurements of the atmospheric electrostatic field strength	216
18. Measurements of the electrostatic field variations	218
19. Measurements of the electrostatic field strengths in the free atmosphere	222
a) Field measurements with balloons, dirigibles and sondes	223
b) Field measurements by airplanes	232
20. Dynamic electrometers	245
a) General characteristics of dynamic electrometers	245
b) Dynamic electrometer designs with rotating electrodes	249
c) Dynamic electrometer designs with vibrating electrodes	253
Chapter 5. Measurements of the concentration and mobility of atmospheric ions	262
21. Method of measuring the ion content of the atmosphere	263
a) Theory of the method	263
b) Analysis of the main features of the counter	267
c) Methods of calculating the conduction current	271
d) Measurements by the charge and discharge methods. The fringe effect	272

Chapter 5a (cont'd)

22. Instruments for measuring the concentration and mobility of ions	276
a) Light-ion counters	276
b) Heavy-ion counters	280
c) Ion spectrometers	285
d) Measurements in the atmosphere	290
Chapter 6. Measurement of the charges of individual particles in the atmosphere	292
23. Direct measurement method	292
24. Induction method	298
25. Method of the deflection of a charged particle in an electric field	303
Chapter 7. Measurement of atmospheric conductivity	313
26. Theory of the method	313
27. Instruments for measuring atmospheric conductivity	316
28. Characteristics of conductivity measurements in the free atmosphere	325
29. Indirect methods of measuring conductivity	328
30. Methods of measuring the gradients of conductivity and ion concentration in the atmosphere	328
a) Measurement of the ratio of conductivities	329
b) Measurement of the conductivity gradient	331
c) Measurement of the gradient of ion concentration	333
Chapter 8. Measurement of volume charges	335
31. Determination of volume charges by the variation of the potential or its gradient with height	335
32. The Thomson (Kelvin) method	339
33. The V. N. Obolenskii cotton batting filter method	343
34. Determination of the volume charges by the ion spectrum	345
Chapter 9. Measurements of electric currents in the atmosphere	347
35. Measurements of the vertical current in the atmosphere	348
a) Measurement of the conduction current	348
b) Measurement of the total vertical current	349
36. Measurements of the current of precipitations	358
37. Measurements of a current from point sources	364
Chapter 10. Measurements of the permittivity of air	371
38. Direct-current measurement of the permittivity of air	371
39. Radio-frequency measurement of the permittivity of air	378
40. Optic-frequency measurement of the permittivity of air	389
41. Determination of the permittivity of air on the basis of temperature, pressure and humidity data	391
Chapter 11. Measurement of thunderstorm electricity.	
Measurement of atmospherics	393
42. Measurements of the electrostatic fields and cloud charges during thunderstorms	394

INTRODUCTION

Wall's proposal (1708) that a spark and a lightning flash are identical could not be verified for many years, because there were no instruments and methods of direct measurement. Detailed study of atmospheric electricity was begun by M. V. Lomonosov, G. V. Rikhman, T. Dalibard and other scientists, who were able to show the electric nature of thunderstorm phenomena such as lightning and thunder and who developed the necessary apparatus for such studies. For example, Rikhman constructed the world's first electrometric instrument designed for such measurements, an electroscope for measuring "electric force." By means of this electroscope, which was the best electrometric instrument of the time, and Lomonosov's "thunder machine," it was established that atmospheric electricity also exists in absence of thunderstorm clouds. This fact formed the basis for an entire branch of atmospheric electric research.

The development of science and technology, chiefly meteorology, aviation, electronics and radio engineering and their numerous subdivisions, has greatly expanded our knowledge of atmospheric electricity.

High, conductive layers of the atmosphere were discovered, namely the ionosphere; powerful sources of atmospheric ionization were revealed, viz. cosmic rays; the electric nature of polar aurorae was established, etc. Investigations of the electric properties of the entire atmosphere were begun. At present, ever greater attention is being paid the study of the electric properties of the atmosphere, because of the demands of the most diverse branches of theoretical and applied science.

To arrive at a reliable forecast of thunderstorms and the tendencies of thunderstorm processes, one must know the laws of cloud charges, chiefly those of thunderstorm clouds. This is required to safeguard the ever expanding network of high-power transmission lines, to insure radio communications, especially aircraft radio communications, since radio interference during flights in clouds and precipitation increases as the third power of the flight speed, and the flight speeds of modern airplanes are being increased continually. Exploratory geophysics, which is greatly extending the search for radioactive ores, encounters the electrical properties of the atmosphere. Upper atmospheric flights are also concerned with these same problems.

With the expansion of investigations has come the demand for development of instruments and methods of observing atmospheric electricity. At present, extensive study is being devoted to such electrical properties of the atmosphere as conductivity, permittivity, the distribution of ion mobilities (ion spectrum), the charges of individual particles and volume charges, electrostatic and electromagnetic fields, electric currents, electron concentration in the ionosphere, the strength of various sources of ionization, cosmic radiation, terrestrial and atmospheric radioactivity, electrification during the disintegration of particles (ball-electric effect) and during phase conversions of water, etc.

In conducting such investigations, one must use apparatus which will take into account a number of the specific properties of atmospheric electric measurement. One of these special features is the exceptionally wide range of measurable values. For example, the vertical currents in the atmosphere may vary from hundreds to hundreds of thousands of amperes. Conductivity changes from 10^{-6} to 10^{-4} ohm $^{-1}$ at the earth's surface to 10^7 - 10^8 ohm $^{-1}$ at a height of approximately 100 km, etc. Therefore, the measuring apparatus must have a number of sensitivity ranges. The operating principle of the instruments for measuring lightning currents must differ from that of instruments for measuring vertical currents, while instruments for measuring atmospheric conductivity at the earth's surface differ considerably from those used to measure ionospheric conductivity.

Another feature of most atmospheric electric observations is the need for measuring very small currents under complex meteorological conditions: low temperature, high relative humidity, precipitation, etc., while small currents of this type are often difficult to measure even under controlled laboratory conditions.

A characteristic feature of atmospheric-electric measurements is that the investigated phenomenon is not reproducible. This means that the measuring apparatus must be highly accurate, since the measured values cannot be refined by subsequent repetition of the measurements, as can usually be done in laboratory studies. Generally speaking, most atmospheric-electric phenomena cannot be reproduced under laboratory conditions.

In a number of cases, the measurements are seriously complicated by the suddenness and brevity of the phenomena. For example, lightning flashes last from several tens of microseconds to several hundreds of milliseconds and follow each other in time intervals from tens of seconds to tens of

minutes. In this case, the measuring apparatus must be tuned to the correct measurement band during the flash and must be prepared to record the process at any moment. Obviously, such an apparatus is impossible without the highest degree of automation.

It is difficult to make measurements of atmospheric electricity in such poorly accessible regions as the ionosphere and thunderstorm clouds. Often it is dangerous to make measurements in thunderstorm clouds. In any event, measurement conditions are complicated when highly stable, reliable automatically recording apparatus is required.

Finally, many atmospheric-electric investigations involve prolonged continuous measurements which require apparatus that will provide reliable measurements for decades.

Often these complex requirements are imposed simultaneously and thus one must have highly accurate atmospheric-electric measurement apparatuses which employ all the possibilities of measurement technique. Mechanical, tube and dynamic electrometers, electrostatic fluxmeters, ionization chambers, ionized-particle counters, cathode-ray oscillographs (for recording rapid processes), pulse radar devices (for studying the ionosphere) and other devices have been built to study atmospheric electricity. This book may be of interest not only to those directly involved in atmospheric-electric measurements, but also to researchers in other branches of science and technology in which electrostatic measurements, measurements of small currents, et al. are made.

In compiling this book, we have kept in mind that some branches of atmospheric-electric measurement have been treated in detail in special literature (e.g., measurement of ionization and lightning currents), while other branches have only been described in journal articles (e.g., measurement of field strength, vertical currents, atmospheric conductivity, i.e., electrostatic measurements and measurements of weak currents) and we have devoted special attention to subject matter not covered thoroughly in special literature.

Chapter 12 "Investigation of the upper atmosphere" was written by L. G. Makhotkin.
